# 1.4 300

Andre Monteiro

 $Term\ 3,\ 2025$ 

## **Problem Summary**

We have a classroom of 300 students arranged in a  $15 \times 20$  grid. Define:

- A = tallest among the shortest students in each column
- B = shortest among the tallest students in each row

We aim to compare A and B, and illustrate the pattern using smaller sample matrices.

## Sample Matrix 1

$$A = \begin{bmatrix} 2 & 5 & 3 \\ 4 & 1 & 6 \\ 1 & 3 & 2 \end{bmatrix}$$

$$B = \begin{bmatrix} 2 & 5 & 3 \\ 4 & 1 & 6 \\ 1 & 3 & 2 \end{bmatrix}$$

Solution

- In the first matrix, A = 2.
- In the second matrix, B = 3.

### Sample Matrix 2

$$A = \begin{bmatrix} 7 & 4 & 5 \\ 3 & 6 & 2 \\ 1 & 5 & 6 \end{bmatrix}$$

$$B = \begin{bmatrix} 7 & 4 & 5 \\ 3 & 6 & 2 \\ 1 & 5 & 6 \end{bmatrix}$$

Solution

- In the first matrix, A = 4.
- In the second matrix, B = 6.

A < B

#### Proof

- For each column, we found the shortest student. Then A is the tallest among these. So A is bigger than or equal to any of the column minima.
- $\bullet$  For each row, we found the tallest student. Then B is the shortest among these. So B is smaller than or equal to any of the row maxima.

Now, look at any student in the grid. Each student is \*\*at least as tall as the shortest in their column\*\* and \*\*at most as tall as the tallest in their row\*\*.

This means the tallest of all column minima (A) can never be taller than the shortest of all row maxima (B), and since we also apply the restriction:

$$A \neq B$$

We can therefore state that no matter how the students are arranged:

$$A < B, (A \neq B)$$

The previous examples make this clear in practice: green (A) is always less than red (B).
